

SUMMARY

The Sales Performance Analysis project is developed using Microsoft Excel to analyse and visualize retail sales data effectively. The main objective of this project is to track sales performance, profit, quantity, and regional trends using interactive charts, formulas, and dashboard elements.

The project uses datasets containing information about orders, products, customers, stores, staffs, and order items. Excel features such as Pivot Tables, Pivot Charts, formulas, conditional formatting, and slicers were used for data cleaning, analysis, and dashboard creation. Important metrics like Total Sales, Total Orders, Total Quantity, and Average Profit were calculated using Excel formulas.

Different visualizations such as bar charts, line charts, pie charts, KPI cards, and summary tables were created to represent business performance clearly. Interactive slicers and filters help users analyse sales data based on regions and product categories, making the dashboard more user-friendly and dynamic.

This project helped in improving skills in Microsoft Excel, data analysis, dashboard design, data visualization, and business analytics. Overall, the dashboard provides meaningful insights that support better business decision-making and performance evaluation.
